

Hobbeast — Business Request Summary — v1.9.5

Date: 2026-08-24 | Release: 1.9.5 | Theme: configuration audit, trip planner restored

Business request

The tour/route planner told users to “set an environment variable” instead of showing a map. Audit every feature that depends on configuration keys, test each one, and supply every missing key so no more features silently fail like this.

What was delivered

- Complete inventory of every configuration key the product references (frontend and backend), compared against what was actually configured — the backend had NO provider keys at all.
- Recovered the customer's own keys from their notes, code history and cloud accounts; every key was validated with a live API call before being stored. Maps, place search (external and database-backed), route planning, elevation profiles and AI event generation are all keyed now.
- Two hidden backend bugs fixed that would have kept the trip planner broken even with keys: a database-safety rule rejected two maintenance functions, and the elevation service was called with the wrong HTTP method.
- Proof: a Budapest–Normafa route plan returns 14.5 km with 508 route points and a full elevation profile; venue search returns live results in both provider and database modes.

Open items (need operator accounts)

Ticketing providers (Ticketmaster, SeatGeek, Eventbrite), push/e-mail delivery service and SMTP still need credentials only the owner can create; the affected features fail cleanly until then. Two keys exposed in old public code history should be rotated at the providers.
